# Immunosuppressive Glycodelin A is an independent marker for poor prognosis in endometrial cancer

Miriam Lenhard<sup>1\*</sup>, Sabine Heublein<sup>2</sup>, Christiane Kunert-Keil<sup>3</sup>, Thomas Vrekoussis<sup>2</sup>, Isabel Lomba<sup>2</sup>, Nina Ditsch<sup>1</sup>, Doris Mayr<sup>4</sup>, Klaus Friese<sup>1,2</sup> and Udo Jeschke<sup>2</sup>

## Abstract

**Background:** Knowledge on immunosuppressive factors in the pathogenesis of endometrial cancer is scarce. The aim of this study was to assess Glycodelin (Gd) and its immunosuppressive isoform Glycodelin A (GdA) in endometrial cancer tissue and to analyze its impact on clinical and pathological features and patient outcome.

**Methods:** 292 patients diagnosed and treated for endometrial cancer were included. Patient characteristics, histology and follow-up data were available. Gd and GdA was determined by immunohistochemistry and in situ hybridization was performed for Gd mRNA.

**Results:** Endometrial cancer shows intermediate (52.2%) or high (20.6%) expression for Gd in 72.8%, and GdA in 71.6% (intermediate 62.6%, high 9.0%) of all cases. The glycosylation dependent staining of GdA is tumour specific and correlates with the peptide-specific Gd staining though neither of the two is associated with estrogen receptor, progesterone receptor or clinic-pathological features. Also Gd protein positively correlates with Gd mRNA as quantified by in situ hybridization. Gd positive cases have a favourable prognosis ( $p = 0.039$ ), while GdA positive patients have a poor outcome ( $p = 0.003$ ). Cox-regression analysis proofed GdA to be an independent prognostic marker for patient survival ( $p = 0.002$ ), besides tumour stage, grade and the concomitant diagnosis of hypertension.

**Conclusion:** Gd and GdA are commonly expressed in endometrial cancer tissue and seem to be of relevance in tumourigenesis. They differ not only in glycosylation but also in their biological activity, since only GdA holds prognostic significance for a poor overall survival in endometrial cancer patients. This finding might be explained by GdAs immunosuppressive capacity.

**Keywords:** Endometrial cancer, Glycodelin, Glycodelin A, Immunohistochemistry, In situ hybridization, Prognosis

## Background

Endometrial cancer is the fourth common carcinoma in women following cancer of breast, colon and lung and accounts for 5.6% of all malignancies [1]. The diagnosis of endometrial cancer is typically made at postmenopausal age [2] and its 5-year survival ranges between 75 and 83% [2].

Some risk factors for the development of endometrial cancer have been described [3-8], though the exact

mechanisms in tumourigenesis are by far not explained. A fast tumour progression is most likely favoured by local immunosuppression, which decreases the body's own anti-tumour immunoreactivity. Until today little is known about tumour induced, local immunosuppression in endometrial cancer.

Glycodelin (Gd), also known progestagen-associated endometrial protein, is a glycoprotein with immunosuppressive capacity, which is mainly produced in reproductive tissue [9,10]. Four different isoforms have been described: GdS (in seminal vesicles and seminal plasma) [11], GdA (in endometrium/decidua, amniotic fluid, maternal serum) [12,13], GdF (in follicular fluid und oviduct) [14] und GdC (in the cumulus oophorus) [15].

Full list of author information is available at the end of the article

The isoforms share a common protein backbone but differ in glycosylation and biological activity [16,17].

GdA holds several immunosuppressive abilities, which are best characterized in reproductive medicine [18]. These include the suppression of lymphocyte proliferation and inhibition of T- and B-cell activity [19-21]. Moreover, the induction of apoptosis via GdA has been investigated [22].

Recently, we found GdA to be of prognostic significance in ovarian cancer [23]. So far, there are very few results on endometrial cancer cells and Gd or GdA [24] and no clinical data on endometrial cancer. Therefore, the aim of this study was to assess the expression of Gd on mRNA and protein level. Further, we aimed to specify the proportion of the immunosuppressive glyko-modification GdA in tissue samples of a large cohort of endometrial cancer patients by using an extensively validated anti GdA antibody. Finally, we aimed to analyse the impact of Gd/GdA positivity on clinical and pathological features including patient outcome.

## Methods

### Patients

Formalin fixed paraffin embedded (FFPE) tissue of 292 endometrial cancer patients (Table 1) was available. Most patients presented with early stage disease at primary diagnosis (Table 1). 72.6% of patients ( $n = 212$ ) showed a Type I carcinoma with endometrioid histology. Among the remainder there were 7.9% with serous, 4.1% with mucinous, 1.7% with clear cell histology and 0.3% with squamous cell histology. 11.6% were classified as mixed and 1.7% as undifferentiated carcinomas. Patients were also evaluated for concomitant diseases and presented with hypertension in 39.7%, obesity in 30.5% and diabetes in 11.3% of all patients.

### Assay methods

#### Immunohistochemistry

Immunohistochemical (IHC) staining has been described previously by us [23,26,27]. Glycosylation dependant staining differences were assessed using the polyclonal Gd and the monoclonal GdA antibody (A87-B/D2) [28]. Specificity of GdA binding was analyzed by Western blot analysis [29-31]. This antibody is suitable for the detection of GdA in endometrial tumour tissues [26]. Our former investigation showed that A87-B/D2 seems to be less restricted to GdA carbohydrate structures than other monoclonal antibodies made in our laboratories, although none of the three monoclonal antibodies recognize GdS or other pregnancy-related glycoproteins such as hCG or transferrin isolated from amniotic fluid [26].

Formalin fixed paraffin embedded tissue sections were dewaxed with xylol and endogenous peroxidase activity was quenched by dipping in 3% hydrogen peroxide (Merck, Darmstadt, Germany) in methanol for 20 min.

Then sections were rehydrated in descending concentrations of alcohol. For GdA staining epitope retrieval was performed in a pressure cooker using sodium citrate buffer (5 min, pH 6.0). Following PBS washes samples were blocked as described in Table 2 and incubated with the primary antibodies (Table 2). Then samples were further processed as per manufacturer's instructions. Finally, immunoreactivity was visualized using diaminobenzidine (Dako, Glostrup, Denmark), slides were counterstained using haematoxylin, dehydrated in ascending concentrations of alcohol, xylol treated and covered. Positive (placenta tissue) and negative (species matched pre-immune sera) controls were always included in the analysis (Additional file 1).

#### Preparation of riboprobes

Preparation of riboprobes was performed as described previously [27,33]. In short, a 227-bp fragment of the Gd cDNA (positions +41 to +268) was cloned into the EcoR1 restriction sites of pBluescript SK (Stratagene, Amsterdam, The Netherlands) and labelled with digoxigenin (DIG) by in vitro transcription using the DIG RNA labeling Kit (SP6/T7; Roche Biochemicals, Mannheim, Germany). The antisense cRNA probe binds *in situ* to Gd-mRNA and was utilized for Gd-mRNA detection. The sense cRNA probe was used as negative control.

#### In situ hybridization

Non-radioactive *in situ*-hybridization (ISH) analysis of Gd was performed on paraffin sections as described previously [27,28,34]. Briefly, paraffin sections were deparaffined, rehydrated and permeabilized by pepsin digestion (750 mg/ml pepsin in 0.2 M HCl, 37°C, 30 min). Postfixation (paraformaldehyde 4%, 20 min, 4C) was followed by acetylation using 0.25% acetic anhydride in triethanolamine (0.1 M, pH 8.0, 15 min). After dehydration in an ascending series of alcohol, the sections were hybridized for 16 hr (56°C) in a solution containing 50% formamide, 50% solution D (4 M guanidine thiocyanate, 25 mM sodium citrate, pH 7.0), 0.5% blocking reagent, 210 mg/ml t-RNA derived from *E. coli* MRE 600, and 125 ng DIG-labeled cRNA probe. After washing with decreased concentrations of SSC (203 SSC: 3 M NaCl, 0.3 M sodium citrate, pH 7.4), sections were incubated 1 hr with blocking reagent (all from Roche Biochemicals).

Bound riboprobe was visualized by incubation with alkaline phosphatase-conjugated anti-DIG antibody (Roche Biochemicals) and subsequent substrate reaction using 5-bromo-4-chloro-3-indolyl phosphate/nitroblue-tetrazolium chloride [27,28,34].

#### Specimen characteristics

All tissue samples ( $n = 292$ ) were gained at surgery in patients who had been treated for primary endometrial

cancer at our institution between 1990 and 2001. Histological evaluation including tumour staging and grading were performed by an experienced gynaecologic pathologist (D.M.) according to the criteria of the International Federation of Gynaecologists and Obstetricians (FIGO) and the World Health Organization (WHO).

### Study design

Tissue samples of endometrial cancer tissue gained at surgery at the Department of Obstetrics and Gynaecology of the Ludwig-Maximilians University Munich between 1990 and 2001 were randomly retrieved from the archive. FFPE material was stained for Gd, GdA or underwent ISH for Gd mRNA; clinical data were analysed retrospectively. Patients with uterine sarcoma were excluded from the study. Patient's clinical data (Table 1) were available from patient charts, aftercare files and tumour registry database information. Mean follow-up time was 13.8 years (95% CI: 13.1-14.5) with 160 deaths. Mean overall survival was 13.6 years (95% CI: 12.6-14.6). The outcome assessed was patient survival.

The study has been approved by the ethics committee of the Ludwig-Maximilians University Munich (approval number: 063-13) and has been carried out in compliance with the guidelines of the Helsinki Declaration of 1975.

### Statistical analysis methods

Statistical analysis was performed using SPSS 20.0 (PASW Statistic, Ehningen, Germany). The non-parametric Kruskal-Wallis rank-sum test and for pairwise comparisons the non-parametric Mann-Whitney-U rank-sum test were used to test for differences between groups. Correlation analysis was performed using Spearman correlation. For the comparison of survival times, Kaplan-Meier curves were drawn. The chi-square statistic of the log-rank test was calculated to test differences between survival curves for significance. Multivariate analysis for prognostic value was performed using the Cox-regression model. Mean values are displayed ± standard error and p values below 0.05 were considered statistically significant.

Immunohistochemical staining was assessed using a semiquantitative immunoreactive score (IRS) according to Remmele and Stegner [35]. The IRS, ranging from 0

**Table 2 Immunohistochemistry: Antibodies detecting Gd or GdA were published by Jeschke et al. 2006 [26] and Jeschke et al. 2005 [32], respectively**

Antibody	Host/clonality	Epitope retrieval	Blocking	Dilution/incubation	Negative control	Reaction system
Gd [32]	Rabbit/ polyclonal	Not performed	Reagent 1 (5 min)	1: 800 (diluted in Dako antibody diluent)/o.n. (4°C)	Rabbit pre-immune serum (Dako)	Vectastain elite (rabbit IgG) kit (Burlingame, CA)
GdA [26]	Mouse/ monoclonal	Citrate buffer (5 min, pressure cooker)	1.5% horse serum (20 min)	1:2000 (diluted in Dako antibody diluent)/o.n. (4°C)	Mouse pre-immune serum (Dako)	Vectastain elite (mouse IgG) kit (Burlingame, CA)

to 12, multiplicates staining intensity (graded as 0 = no, 1 = weak, 2 = moderate, and 3 = strong staining) and the percentage of positively stained cells (0 = no, 1 ≤ 10%, 2 = 11–50%, 3 = 51–80% and 4 ≥ 81% cells). The slides were reviewed in a blinded fashion by two independent observers. Intermediate positivity was set as median IRS ± one IRS unit, while low to negative immunoreactivity was assumed for IRS ≤ median IRS - two IRS units and high positivity was attributed for IRS ≥ median IRS + two IRS units (Additional file 2).

Gd mRNA expression was analysed automatically in a computer aided procedure as published previously by our group [27,28,34]. Briefly, five digital pictures were taken randomly from each tissue section (3CCD color camera, HV-C20M, Hitachi, Denshi, Japan, and Axiolab, Carl Zeiss, Jena, Germany). Optical density of white background colour was attuned to 250 to standardize measurements. Mean optical density and Gd positive pixels were determined by KSRUn software (imaging system KS400, release 3.0, Zeiss). In accordance to the IRS system Gd positive pixels were ranked in nine groups representing lowest (group 1) to highest (group 9) Gd mRNA expression.

## Results

Endometrial cancer tissue of 292 patients (Table 1) was available. Data of 291 cases analysed for Gd, 289 cases stained for GdA and 254 cases analysed for Gd mRNA were included in the statistical analysis. Remaining cases (IHC: Gd: n = 1, GdA: n = 3 and ISH: Gd mRNA: n = 38) had to be excluded due to technical reasons. Mean patient age at primary diagnosis was  $65.1 \pm 0.6$  years (range 35–88 years) and further patient characteristics are listed in Table 1.

### Gd mRNA expression in endometrial cancer tissue

Intermediate (37.8%) or high (24.0%) expression of Gd mRNA (PAEP, progestagen-associated endometrial protein) was detected in the majority of cases investigated here (Figure 1). Though mRNA in situ hybridization revealed Gd transcripts to predominantly localize to the tumour epithelium, no significant difference in Gd mRNA expression was detected among histological tumour subtypes (Figure 1). In the current study positivity for Gd mRNA was neither statistically associated with histological tumour grade nor with the patients' FIGO stage.

### Gd and GdA in endometrial cancer tissue

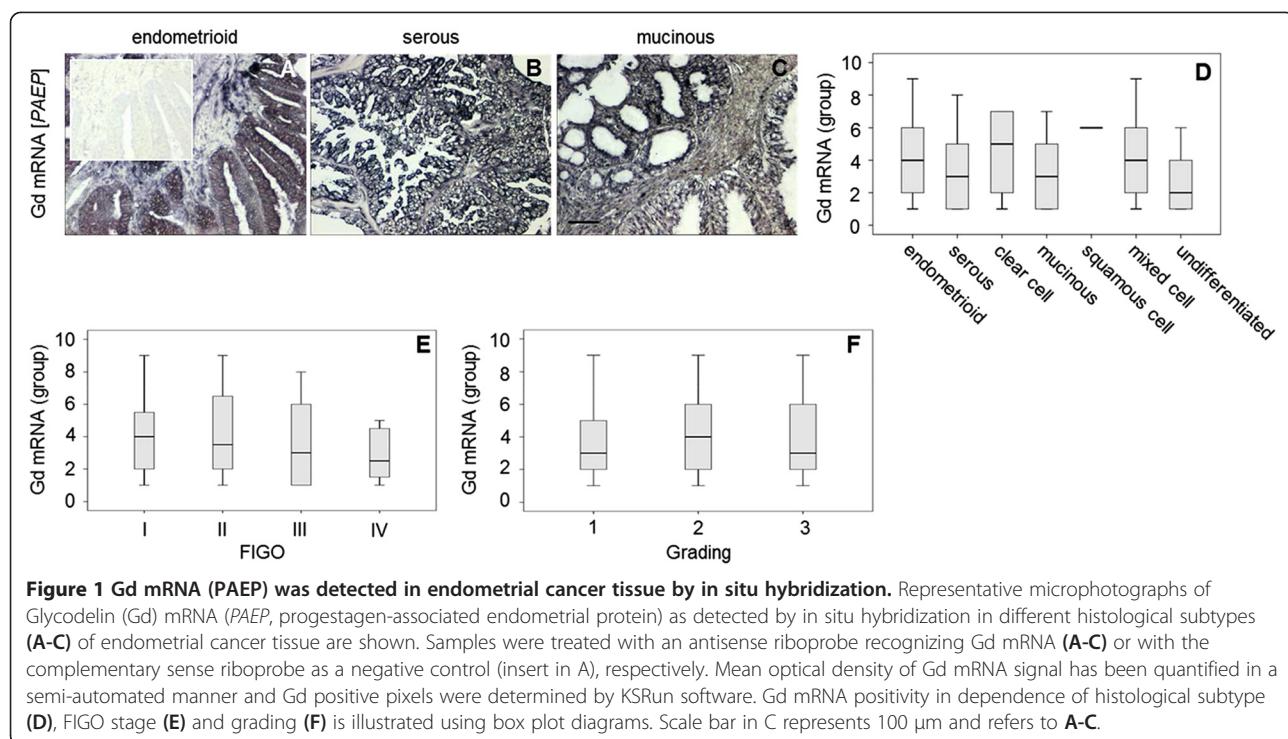

Using a polyclonal antiserum we also proofed presence of Gd protein in endometrial tissue. Immunohistochemical staining showed endometrial cancer tissue to be intermediately or highly positive for Gd in 52.2% or 20.6% (Figure 2, Table 1), respectively. A significant proportion of endometrioid carcinoma cases were observed to produce an immunosuppressive Gd glycomodification, termed GdA. The latter was present at intermediate or high levels in 62.6% or 9.0% of cases, respectively. Inspite the fact that immunoreactivity for the Gd protein was positively correlated with Gd mRNA expression (Correlation coefficient 0.155, p = 0.013), no such association was observed when Gd mRNA was correlated with the glyco-variant GdA. However, GdA immunoreactivity was closely correlated with Gd protein expression (Correlation coefficient 0.249, p < 0.001).

The highest median Gd expression was noted for the undifferentiated histological subtype (median IRS 8.0; mean IRS  $7.80 \pm 0.49$ , Additional file 3), followed by the endometrioid (median IRS 6.0; mean IRS  $5.9 \pm 0.23$ ), the serous (median IRS 6.0; mean IRS  $5.74 \pm 0.76$ ) and the mixed cell type (median IRS 6.0; mean IRS  $4.97 \pm 0.60$ ), though differences among Gd expression and the histological subtypes did not reach statistical significance (p > 0.05) (Figures 2 and 3). Comparable results were observed for GdA expression and the histological subtype (Figure 2 and 3). The most common histological subtypes (endometrioid and serous) show median GdA expression of IRS 6.0. Also, no statistically significant differences in GdA expression were observed among the different histological subtypes (p > 0.05) (Figures 2, 3 and Additional file 3).

Interestingly, there is a significant reduction in Gd expression observed from FIGO III to FIGO IV (p = 0.044) (Figure 3). However, overall Gd/GdA immunoreactivities comparing cases of low vs. high FIGO stage were not significantly different (Additional file 4). There were no significant differences in Gd and GdA expression between different tumour grades (Figure 3). Immunoreactivity of Gd or GdA staining was not significantly different comparing cases being negative vs. positive for ERs, PRs or co-morbidities.

### Prognostic value

Statistical analysis was also performed to test for a prognostic value of Gd or GdA expression. Univariate Kaplan

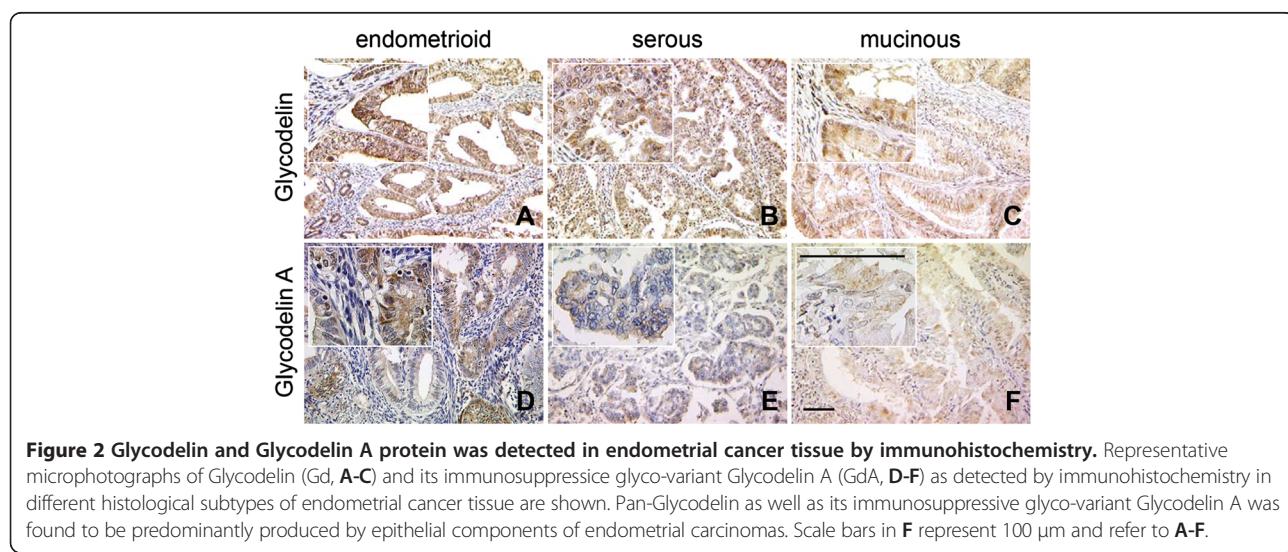

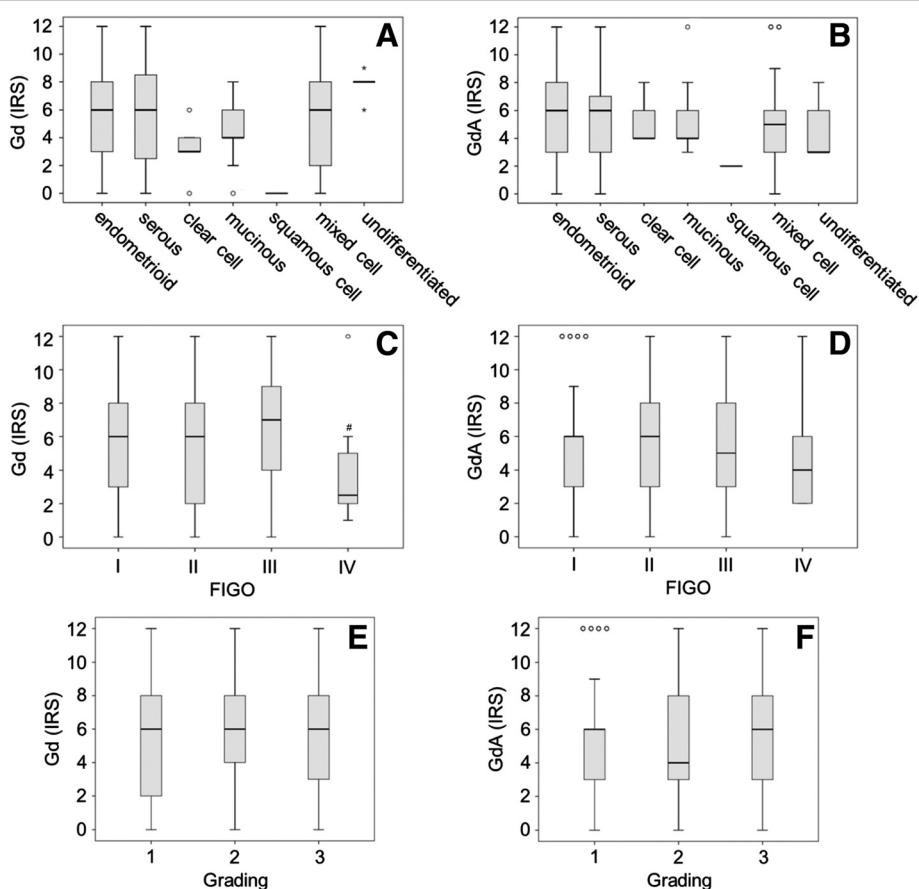

Meier analysis revealed a good prognosis for intermediate and high Gd expression ( $p = 0.039$ ) (Figure 4A). In contrast, highly positive GdA endometrial cancer patients had a poor outcome compared to intermediate and low GdA expression ( $p = 0.003$ ) (Figure 4B). Gd mRNA expression was not significantly associated with patients' outcome.

Besides tumour stage, grade and the concomitant diagnosis of hypertension (each  $p < 0.05$ ), Cox-regression analysis (Table 3) showed GdA to be an independent prognostic marker for patient survival ( $p = 0.002$ , 95% CI 1.362-3.943).

## Discussion

Endometrial cancer can be subdivided into two histological subtypes, the estrogen-associated Type I and the estrogen-independent Type II carcinoma [36,37]. The most common cause for endometrial Type I carcinoma is thought to be an excess of estrogens, which are inadequately antagonized by gestagens [38]. Therefore obesity, polycystic ovarian syndrome, menopausal hormone use are associated with a higher risk for endometrial cancer [3-5]. The Type II carcinoma, which comprises mostly the serous and clear cell histological subtypes, is

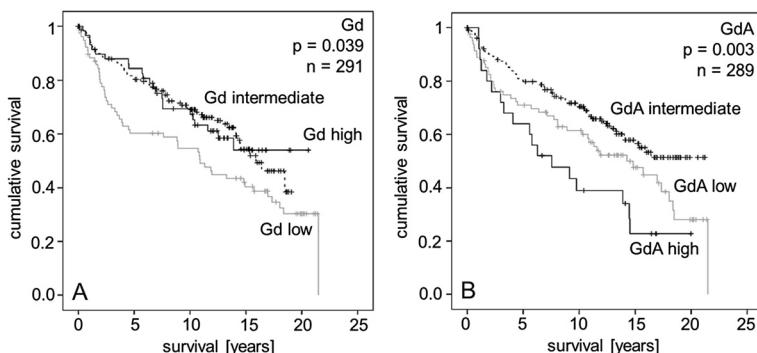

**Figure 3** Glycodelin as well as its immunosuppressive glyco-variant Glycodelin A protein was analysed and quantified in endometrial cancer tissue. Quantification of Glycodelin (Gd; A, C, E) and its immunosuppressive glyco-variant Glycodelin A (GdA; B, D, F) by immunohistochemistry is shown. Gd/GdA was visualized in endometrial carcinoma tissue of different histological subtypes (A, B), FIGO stages (C, D) or tumour grades (E, F). Gd and GdA were detected by immuno-histochemistry and quantified employing an immunoreactive score (IRS) ranging from 0 (lowest) to 12 (highest). Significant differences ( $p < 0.05$ ) as determined by Mann-Whitney Test are indicated by #.

known to metastasize more often and to have a worse survival. In contrast to endometrial Type I carcinomas estrogen dominance does not seem to be causally linked to this type of the disease, rather higher age and previous radiation therapy of the uterus [39].

The majority of cases are classified as Type I carcinoma and comprise the endometrioid adenocarcinomas. In literature it accounts for 75-85% of all adenocarcinomas [36,37,40], which is in accordance with our study population of 72.6% endometrioid tumours.

**Figure 4** Kaplan Meier survival analyses were performed for Glycodelin and Glycodelin A in endometrial cancer patients. Overall survival of patients with low, intermediate and high Glycodelin A (A) and Glycodelin (B) protein expression as detected by immunohistochemistry is shown.

Significant results are shown in bold.

Interestingly, we found the concomitant diagnosis of hypertension to be a negative predictor in patients diagnosed with endometrial cancer. This finding is in accordance with newly published data by Nicholas et al., who reported diabetes and hypertension to adversely affect survival and demanded to give more attention to comorbidities, since they are gaining more influence on current health care and policy [41].

Though Gd has been identified in a range of different tissue types, not all of them do indeed synthesize the protein, which is made evident by the presence and absence of Gd mRNA [14,15,42,43]. Our immunohistochemistry results were confirmed by *in situ* hybridization showing not only the presence of Gd in endometrial cancer but also its synthesis and thus underline its role in carcinogenesis. To our best knowledge this is the first study

reporting Gd to be present on both mRNA and protein level in endometrial cancer. Moreover, existence of Gd mRNA and its close correlation to Gd protein immunoreactivity suggests that endometrial cancer cells themselves possess the ability to synthesize the Gd protein. Interestingly, no significant association of Gd mRNA and the immunosuppressive Gd glyco-epitope GdA was observed, implying that GdA positivity marks a subfraction of endometrioid cancer that cannot be predicted by sole presence of Gd mRNA. Unfortunately, due to the very limited amount of tissue available protein extraction and western blot analysis, which would allow direct quantification of Gd/GdA of the same sample, was not possible.

In hormone-dependent tumours, Gd has been described to have various effects through reduced expression of oncogens and raised expression of tumour suppressor

genes. Among these Gd induced changes are reduced tumour growth, decreased metastatic properties or decreased chemoresistance [24,44]. Hautala et al. showed glycodelin to reduce breast cancer tumour growth *in vivo* [44]. Koistinen et al. transfected endometrial adenocarcinoma HEC-1B cells with Gd cDNA in both antisense and sense orientations [24]. They observed sense-transfected, Gd-producing carcinoma cells to have a reduced proliferation, morphologic changes, and altered expression of cancer-related genes in comparison to native and antisense-transfected carcinoma cells [24]. These results illustrate some aspects of Gd's potential in gynecological cancers. In some hormone-depending tumours, Gd expression has been shown to go along with a favourable outcome, like in breast and ovarian cancer [45,46]. Results on ductal carcinoma *in situ* and invasive breast revealed that Gd positivity is inversely correlated with the occurrence of metastasis [45]. These data are in line with our findings, though Gd expression reached only univariate prognostic significance in Kaplan Meier analysis.

Recently histone deacetylase inhibitors (HDACIs) have been highlighted as promising new anti-cancer agents. In 2006 the HDACI suberoylanilide hydroxamic acid (SAHA, Vorinostat (rINN), Zolinza<sup>®</sup>) has been approved by the FDA for the treatment of cutaneous T-cell lymphoma and has further been evaluated in patients suffering from e.g. glioblastoma multiforme [47], non-small-cell lung [48] cancer or myelodysplastic syndromes [49]. Uchida et al. [50-52] demonstrated that SAHA is capable of up-regulating Gd in endometrial cancer and choriocarcinoma cell lines and further that SAHA induced Gd in fact influences cell differentiation and migration in the model system employed. Since we found that Gd is significantly associated with prolonged overall survival in endometrial cancer, it remains challenging to investigate whether endometrial cancer patients might also benefit from the application of SAHA. Of course randomized and properly powered clinical trials are indispensable in order to validate this hypothesis on a clinical basis.

Depending on Gd glycosylation status, it can induce apoptosis in T cells and monocytes. These *in vivo* results on Gd and GdA may explain the partially contradictory results in clinical studies. In contrast to Gd, we observed a poor outcome in patients expressing the immunosuppressive isoform GdA. This result was made not only on the basis of univariate but also multivariate survival analysis and is in concordance with a recently published study on ovarian cancer and GdA, where we report GdA to be a prognostic marker for poor outcome in advanced stage ovarian cancer [23]. Nevertheless, there are controversial results on Gd expression and patient survival [23,45,46,53]. These may be attributable to various mono- and polyclonal antibodies being either peptide-specific or glycosylation specific. Bearing in mind that differently glycosylated Gd

isoforms may exert opposing actions may at least partially explain the conflicting research results published on this issue [54]. Functional analysis e.g. employing an endometrial cancer animal model is thus needed to further clarify the immunomodulatory actions of Gd/GdA.

## Conclusion

In conclusion, Gd and GdA are commonly expressed in endometrial cancer tissue and seem to be of relevance in tumourigenesis. They differ not only in glycosylation but also in their biological activity, since Gd is associated with a better survival, whereas GdA holds prognostic significance for a poor outcome in endometrial cancer patients. Therefore, Gd and especially GdA might help to select patients for a more individualized tumour therapy.

## Consent

As stated above the current study has been approved by the ethics committee of the Ludwig-Maximilians University Munich (approval number: 063-13) and has been carried out in compliance with the guidelines of the Helsinki Declaration of 1975. All specimens included in this study were left over samples collected during routine clinical diagnostics. Patient data were fully anonymised and the current study has been approved by the ethics committee of the LMU Munich.

## Additional files

### Additional file 1: Representative microphotographs of positive (A, B) and negative controls (C, D) for Gd (A, C) and GdA (B, D) are shown.

Placental tissue was either incubated with the respective antibodies detecting Gd (A) or GdA (B) or with the respective species matched pre-immune sera (C, D). Scale bar in A equals 100 μm and applies to A-D.

### Additional file 2: Representative microphotographs of Gd (A, C) and GdA (B, D) in strongly (A, B; high IRS) and weakly/negatively (C, D; low IRS) stained tissue samples are shown. Scale bar in A equals 100 μm and applies to A-D.

### Additional file 3: Representative microphotographs of Gd (A) and GdA (B) in endometrial cancer samples of undifferentiated histology are presented. Scale bar in A equals 100 μm and applies to A, B.

### Additional file 4: Representative microphotographs of Gd (A, C) and GdA (B, D) in advanced (A, B; high stage) and early (C, D; low stage) staged cases are shown. Scale bar in A equals 100 μm and applies to A-D.

## Competing interest

All authors declare to have no financial or non-financial competing interests. There is no funding source to be disclosed.

## Authors' contributions

ML, CKK, IL made substantial contributions to conception, design and acquisition of data. SH and DM have made substantial contributions to analysis and interpretation of data. ND has been involved in drafting the manuscript and revising it critically for important intellectual content. KF and UJ have given final approval of the version to be published. In addition, KF and UJ have made substantial contributions to conception and design of the study. All authors read and approved the final manuscript.

## Acknowledgement

We thank Susanne Kunze and Christina Kuhn for their assistance with immunohistochemistry.

**Submit your next manuscript to BioMed Central and take full advantage of:**

- Convenient online submission
- Thorough peer review
- No space constraints or color figure charges
- Immediate publication on acceptance
- Inclusion in PubMed, CAS, Scopus and Google Scholar
- Research which is freely available for redistribution

Submit your manuscript at
